1. I moved work onto isolates by first marking the generateJson function and the parseJson function as async and making the return type of type Future<>. Then, if _parseGenUsingCompute was true, I would assign bigJson = await compute(fakeExternalGenerateBigJson, count) and parsed = await compute(fakeExternalParseJson, raw).

This would make the functions parseJson and generateJson offload most of their work onto an isolate.

2. There wasn't much of a performance difference in elapsed time with the switch ON or OFF, in both cases the elapse time was around ~800 ms
3. The cost of isolates is that to use the compute function, you are copying over the data that you are passing. So for example when you do compute(fakeExternalParseJson, raw), if that raw string is 1000000 characters long, then you would have to copy it over by value, which is essentially creating a copy, causing a hit in performance.
4. I did not encounter any bugs or edge cases in my testing.
